Digital optical microscopy as a screening tool for polymicrobial aerobic biofilms. Bacteria in biofilms are often multi-species. To identify biofilms containing diverse organisms and to screen for antimicrobial resistance, we developed a digital optical microscopy-based method (ODM) that detects and analyses samples of biofilms on a microtiter plate using a simple syringe and automated imaging. We used this method to assess the species composition of biofilms on intravascular devices and on an in vivo animal model. We found that polymicrobial biofilms (containing five or more organisms) were present on 4.5% of devices and 23.9% of animals. Many organisms within these biofilms demonstrated high levels of antimicrobial resistance (AMR) to multiple antibiotic classes. ODM can detect complex biofilms and can be implemented on any compact, portable, and inexpensive digital optical microscope. ODM is a rapid, low-cost screening tool to identify polymicrobial biofilms, which may help identify the presence of AMR within these biofilms.
