Influence of alginate, cellulose and starch xanthate on the properties of porous two-

component calcium phosphates. The effect of combining two porous calcium phosphate (CaP) powders with a high alumina content with the addition of different bonding agents onto their physical and chemical properties was investigated. Lactic acid (LA) was used to precipitate a new Al(3+)-substituted form of calcium in a new porous form, and the resulting powders were heated in air and used as the bonding agent. In addition, calcium carbonate (CaCO₃) and α-cellulose xanthate (CAX) were used as comparison agents. Fourier transform infrared spectroscopy (FT-IR), X-ray diffraction (XRD) and Brunauer-Emmett-Teller (BET) surface area analysis were used to characterize the materials. The incorporation of the adhesive agents caused an increase in the specific surface area and changes in the micropore structure. The addition of lactic acid to the system increased the quantity of calcium carbonate, while decreasing the ratio of HA in the system. In addition, FT-IR

showed that an interaction occurred between the carboxyl groups of the LA and the apatite group. According to the XRD analysis, the formation of a new form of calcium phosphate (CaO-HPO(4)) on the surface of CaHPO(4) was confirmed. CaO-HPO(4) has a more regular crystal structure than α -TCP; thus, it is possible that the addition of CaO-HPO(4) to the system could decrease the crystallinity of the CaHPO(4). The mechanical properties showed an improvement in the flexural strength and modulus when compared with the one obtained when calcium carbonate was used as an adhesive agent.
