Transplantation options for end-stage chronic heart failure are limited. Cardiac stem cell therapy is a novel non-vascular cell-based therapy with the potential to repair damaged myocardium. The first therapeutic trial in humans demonstrated that autologous cardiac stem cells (CSci) can be transplanted into ischemic myocardium with no apparent adverse effects and are functionally and anatomically integrated. Remarkably, the clinical results were equivalent to those obtained with bone marrow mononuclear cells (BMMNCs), the current clinical standard of care. This clinical effect, however, was restricted to ischemic patients. In the last funding period of this work (P50 HL72674), we provided compelling data that these cells were neither inherently able to survive in the ischemic heart nor differentiate into the desired cardiomyocyte-like cells. From these studies we hypothesized that other stem cell populations, preferentially localized within the heart, may have the potential to better deliver the therapeutic effects of CSci. We found that adult stem cells, particularly cardiac stem cells (CSCs), are present in the myocardium under steady state conditions, being able to contribute to the formation of several cardiac cell types. From these results and other preliminary results, we hypothesized that in ischemic human hearts CSCs, associated with or isolated from the walls of large coronary arteries, are functionally abnormal, unable to survive and provide a therapeutic effect. In the last funding period, we first developed and characterized a reliable cell population enriched in CSCs, using CD133 as a marker of CSCs in the myocardium. Importantly, we showed that CD133+ cells have a robust capacity to proliferate, migrate, and differentiate into functional cardiomyocytes, arterial smooth muscle cells (ASM), and endothelial cells (ECs). The properties of CD133+ cells provide the basis for the development of a new population of cells, from a non-vascular origin, that we refer to as coronary stem cells (CSci), which would have the capacity to propagate in culture. In this study we will test the hypothesis that CSci can be differentiated into either cardiomyocytes or endothelial cells in vitro, showing the potential to serve as a therapy for end-stage chronic heart failure. The first goal of this study is to optimize and validate a novel protocol for the isolation and propagation of CSci for clinical use. Second, we will test the ability of these cells to differentiate
